Antibiotic Resistance – Primary Care: facts and figures

Fact #1
Antibiotic resistance is an increasingly serious patient safety and public health problem in England, Europe and the world [1, 2]. Resistance to antibiotics is increasing. In many countries, resistance rates have more than doubled in five years (Figure 1).

Growing antibiotic resistance threatens the effectiveness of antibiotics now and in the future. Inappropriate use of antibiotics not only leads to resistance which increases the risk of treatment failure, hospitalisation, and cost of care but can also lead to adverse effects such as thrush and diarrhoea caused by *Clostridium difficile* infection.

Fact #2
Antibiotic exposure leads to emergence of antibiotic resistance [4]. The overall uptake of antibiotics in an individual and the population, as well as how antibiotics are consumed, has an impact on antibiotic resistance [5, 6, 7]. The presence of antibiotic resistant bacteria in urinary, respiratory and skin infections in individual patients in primary care has been strongly linked to the number and duration of antibiotic courses prescribed in the previous 12 months [7].

Antibiotic Resistance – Primary Care: facts and figures

Fact #3
In Scotland, primary care accounts for about 80 to 90% of all antibiotic prescriptions, mainly for respiratory tract infections [5, 8]. Antibiotic prescribing and consumption varies between European countries (Figure 3) [9,10].

Fact #4
Communicating with patients is key.
Professional medical advice impacts patients’ perceptions and attitudes towards their illness and perceived need for antibiotics, particularly if they are advised on what to expect in the course of the illness, including realistic recovery time and self-management strategies [12-18].

Studies show that patient satisfaction in primary care settings depends more on effective communication than on receiving an antibiotic prescription [11-13] and that prescribing an antibiotic for an upper respiratory tract infection does not decrease subsequent visits [14].

Primary care prescribers do not need to allocate more time for consultations that involve offering alternatives such as delayed prescriptions or written advice to antibiotic prescribing. Studies show that this can be done within the same average consultation time while maintaining a high degree of patient satisfaction [10, 16, 17].
